EXPERIMENT-2

2. Scenario: You are a data analyst working for a company that sells products online. You have been tasked with analyzing the sales data for the past month. The data is stored in a NumPy array.

Question: How would you find the average price of all the products sold in the past month?

Assume 3x3 matrix with each row representing the sales for a different product

Aim

To calculate the average price of all products sold during the past month using NumPy arrays.

Algorithm

1. Import the NumPy library.
2. Create a 3×3 NumPy array containing the sales data.
3. Use np.mean() to calculate the average of all values.
4. Display the average price.

Code

```
import numpy as np

sales_data = np.array([

   [100, 120, 150],

   [200, 180, 220],

   [150, 170, 160]

])

average_price = np.mean(sales_data)
```

print("Average price of all products:", average_price)

Input

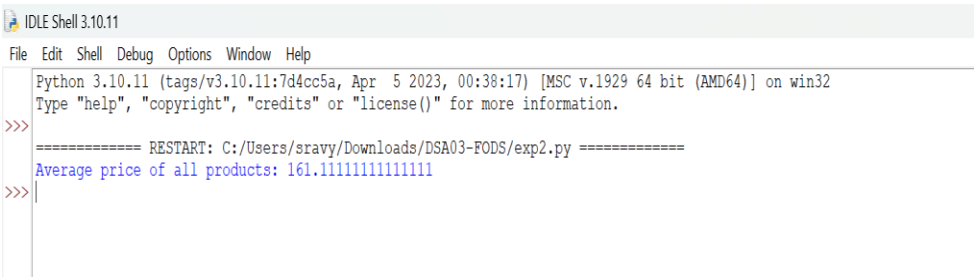

100 120 150

200 180 220

150 170 160

Output

Average price of all products: 161.11111111111111

Result

Thus, the average price of all the products sold during the month was calculated successfully as **161.11**.
